8 Matrix Types

Matrices are useful because they can efficiently represent and manipulate large amounts of data, simplify calculations, and organise complex equations in a compact form.

For example, in undergraduate econometrics, we consider the following linear model:

$$y_i = \beta_0 + \beta_1 x_{i,1} + \beta_2 x_{i,2} + \cdots + \beta_K x_{i,K} + u_i \quad (1)$$

$$= \beta_0 + \sum_{k=1}^K \beta_k x_{i,k} + u_i \quad (2)$$

for  $i = 1, \dots, N$ .

# Stacked Representation

When we stack these equations for  $i = 1, \dots, N$ , we obtain

$$\begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_N \end{pmatrix} = \begin{pmatrix} 1 & x_{1,1} & x_{1,2} & \dots & x_{1,K} \\ 1 & x_{2,1} & x_{2,2} & \dots & x_{2,K} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_{N,1} & x_{N,2} & \dots & x_{N,K} \end{pmatrix} \begin{pmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_K \end{pmatrix} + \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_N \end{pmatrix}.$$

This can be written more compactly as

$$y = X\beta + u,$$

where

$$y, u \in \mathbb{R}^N, \quad X \in \mathbb{R}^{N \times (K+1)}, \quad \beta \in \mathbb{R}^{K+1}.$$

$\mathbb{R}$  denotes the set of real numbers.

# Dimension

If  $x$  is ...

- a scalar,  $x \in \mathbb{R}$ .

This means that  $x$  is a real number.

Example:  $x = 2 \in \mathbb{R}$

- a vector,  $x \in \mathbb{R}^m$ , where  $m$  is a positive integer.

This means that  $x$  has  $m$  elements.

Example:

$$x = \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \in \mathbb{R}^3$$

Transpose of a  
Matrix

Inverse Matrix

Determinant of a Matrix

Inverse Matrix

Matrix Types

- a matrix,  $x \in \mathbb{R}^{\ell \times m}$ , where  $\ell$  and  $m$  are positive integers.  
This means that  $x$  has  $\ell \times m$  entries.

Example:

$$x = \begin{pmatrix} 1 & 4 \\ 2 & 5 \\ 3 & 6 \end{pmatrix} \in \mathbb{R}^{3 \times 2}$$

Here,  $\ell$  is the number of rows and  $m$  is the number of columns.

# General Representation of a Matrix

Let  $X$  be a matrix of dimension  $a \times b$ . The element of  $X$  in the  $i$ -th row and  $j$ -th column is denoted by  $x_{ij}$ , where  $i = 1, \dots, a$  and  $j = 1, \dots, b$ . Then we can write

$$X = \begin{pmatrix} x_{11} & x_{12} & \dots & x_{1b} \\ x_{21} & x_{22} & \dots & x_{2b} \\ \vdots & \vdots & \ddots & \vdots \\ x_{a1} & x_{a2} & \dots & x_{ab} \end{pmatrix} \in \mathbb{R}^{a \times b}.$$

Each element  $x_{ij}$  represents the value in the  $i$ -th row and  $j$ -th column.

A vector can be viewed as an  $a \times 1$  matrix.

# Square Matrix

A square matrix is a matrix with the same number of rows and columns. In other words, a matrix of size  $n \times n$  is called a square matrix.

Example:

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

This is a  $3 \times 3$  square matrix.

# Symmetric Matrix

A matrix  $A$  is called symmetric if it is equal to its own transpose:

$$A^T = A.$$

For a matrix  $A = [a_{ij}]$ , this is equivalent to

$$a_{ij} = a_{ji} \quad \text{for all } i, j.$$

So the entries are mirrored along the main diagonal.

# Example of a Symmetric Matrix

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{pmatrix}$$

This matrix is symmetric because

$$A^T = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{pmatrix} = A.$$

# Diagonal Matrix

A matrix  $D \in \mathbb{R}^{n \times n}$  is called a diagonal matrix if all off-diagonal entries are zero:

$$D = \begin{pmatrix} d_1 & 0 & 0 & \dots & 0 \\ 0 & d_2 & 0 & \dots & 0 \\ 0 & 0 & d_3 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & d_n \end{pmatrix}.$$

Example:

$$D = \begin{pmatrix} 3 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 7 \end{pmatrix}$$

Diagonal matrices are useful for matrix powers, eigenvalue problems, and diagonalisation.

# Identity Matrix

The identity matrix is a square matrix with 1s on the main diagonal and 0s elsewhere. It is denoted by  $I_n$ .

$$I_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The identity matrix satisfies

$$I_n A = A I_n = A$$

whenever the multiplication is defined.

# Idempotent Matrix

A matrix  $A$  is called **idempotent** if

$$A^2 = A.$$

Example:

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

Then

$$A^2 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = A.$$

# Matrix Addition

If  $A$  and  $B$  are matrices of the same dimension  $m \times n$ , then their sum  $C = A + B$  is defined entry by entry:

$$C_{ij} = A_{ij} + B_{ij}.$$

# Example of Matrix Addition

$$A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}, \quad B = \begin{pmatrix} 5 & 6 \\ 7 & 8 \end{pmatrix}$$

Then

$$A + B = \begin{pmatrix} 1 + 5 & 2 + 6 \\ 3 + 7 & 4 + 8 \end{pmatrix} = \begin{pmatrix} 6 & 8 \\ 10 & 12 \end{pmatrix}.$$

# Matrix Subtraction

If  $A$  and  $B$  are matrices of the same dimension, then their difference  $C = A - B$  is defined by

$$C_{ij} = A_{ij} - B_{ij}.$$

# Example of Matrix Subtraction

$$A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}, \quad B = \begin{pmatrix} 5 & 6 \\ 7 & 8 \end{pmatrix}$$

Then

$$A - B = \begin{pmatrix} 1 - 5 & 2 - 6 \\ 3 - 7 & 4 - 8 \end{pmatrix} = \begin{pmatrix} -4 & -4 \\ -4 & -4 \end{pmatrix}.$$

# Properties of Matrix Addition

Let  $A, B, C \in \mathbb{R}^{m \times n}$ . Then:

①  $A + B = B + A$

②  $(A + B) + C = A + (B + C)$

③  $A + \mathbf{0} = A$

④  $A - A = \mathbf{0}$

(commutative)

(associative)

(additive identity)

# Zero Matrix

The zero matrix is a matrix whose entries are all zero:

$$\mathbf{0} = \begin{pmatrix} 0 & \dots & 0 \\ 0 & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & 0 \end{pmatrix}.$$

# Scalar Multiplication

Let  $A$  be an  $m \times n$  matrix and  $c$  a scalar. Then  $cA$  is obtained by multiplying each entry of  $A$  by  $c$ :

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix} \Rightarrow cA = \begin{pmatrix} ca_{11} & ca_{12} & \dots & ca_{1n} \\ ca_{21} & ca_{22} & \dots & ca_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ ca_{m1} & ca_{m2} & \dots & ca_{mn} \end{pmatrix}.$$

# Properties of Scalar Multiplication

For matrices  $A, B$  of the same size and scalars  $c, d$ :

$$\textcircled{1} \quad c(A + B) = cA + cB$$

$$\textcircled{2} \quad (c + d)A = cA + dA$$

$$\textcircled{3} \quad c(dA) = (cd)A$$

$$\textcircled{4} \quad 1A = A$$

# Exercise: Scalar Multiplication

Solve the following:

- ① Compute

$$3 \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}.$$

- ② Verify

$$2 \left( \begin{pmatrix} 1 & 3 \\ 2 & 4 \end{pmatrix} + \begin{pmatrix} 5 & 7 \\ 6 & 8 \end{pmatrix} \right) = 2 \begin{pmatrix} 1 & 3 \\ 2 & 4 \end{pmatrix} + 2 \begin{pmatrix} 5 & 7 \\ 6 & 8 \end{pmatrix}.$$

- ③ Show that  $c(dA) = (cd)A$  for  $c = 2$ ,  $d = 3$ , and

$$A = \begin{pmatrix} 4 & 5 \\ 6 & 7 \end{pmatrix}.$$

# Matrix Operations Practice

Let

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}, \quad B = \begin{pmatrix} 7 & 8 & 9 \\ 10 & 11 & 12 \end{pmatrix}, \quad c = 3.$$

Compute:

①  $A + B$

②  $B - A$

③  $3A$

④  $2A + cB$

# Matrix Multiplication

For two matrices  $A$  and  $B$ , the product  $AB$  is defined only when the number of columns of  $A$  equals the number of rows of  $B$ .

If

$$A \in \mathbb{R}^{m \times n}, \quad B \in \mathbb{R}^{n \times p},$$

then

$$AB \in \mathbb{R}^{m \times p}.$$

In matrix calculations, it is always important to check the dimensions first. The dimensions must be compatible.

# Formula for Matrix Multiplication

If  $A \in \mathbb{R}^{m \times n}$  and  $B \in \mathbb{R}^{n \times p}$ , then

$$AB = \begin{pmatrix} \sum_{k=1}^n a_{1k}b_{k1} & \sum_{k=1}^n a_{1k}b_{k2} & \cdots & \sum_{k=1}^n a_{1k}b_{kp} \\ \sum_{k=1}^n a_{2k}b_{k1} & \sum_{k=1}^n a_{2k}b_{k2} & \cdots & \sum_{k=1}^n a_{2k}b_{kp} \\ \vdots & \vdots & \ddots & \vdots \\ \sum_{k=1}^n a_{mk}b_{k1} & \sum_{k=1}^n a_{mk}b_{k2} & \cdots & \sum_{k=1}^n a_{mk}b_{kp} \end{pmatrix}.$$

# Example of Matrix Multiplication

$$A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}, \quad B = \begin{pmatrix} 5 & 6 \\ 7 & 8 \end{pmatrix}$$

Then

$$AB = \begin{pmatrix} 1 \cdot 5 + 2 \cdot 7 & 1 \cdot 6 + 2 \cdot 8 \\ 3 \cdot 5 + 4 \cdot 7 & 3 \cdot 6 + 4 \cdot 8 \end{pmatrix} = \begin{pmatrix} 19 & 22 \\ 43 & 50 \end{pmatrix}.$$

# Properties of Matrix Multiplication

Let  $A, B, C$  be matrices of compatible dimensions and  $\alpha \in \mathbb{R}$ . Then:

①  $\alpha(AB) = (\alpha A)B$

②  $(AB)C = A(BC)$

③  $A(B + C) = AB + AC$

④  $(A + B)C = AC + BC$

⑤ In general,  $AB \neq BA$

# Identity Matrix Multiplication

For the identity matrix  $I_n$ ,

$$I_n A = A I_n = A$$

whenever the multiplication is defined.

Example:

$$I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad A = \begin{pmatrix} 3 & 4 \\ 5 & 6 \end{pmatrix}$$

Then

$$I_2 A = A.$$

# Transpose of a Matrix

The transpose of a matrix  $A$ , denoted by  $A^T$ , is obtained by interchanging rows and columns.

If  $A$  is an  $m \times n$  matrix, then  $A^T$  is an  $n \times m$  matrix.

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix} \Rightarrow A^T = \begin{pmatrix} a_{11} & a_{21} & \dots & a_{m1} \\ a_{12} & a_{22} & \dots & a_{m2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n} & a_{2n} & \dots & a_{mn} \end{pmatrix}.$$

# Example of a Transpose

Let

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}.$$

Then

$$A^T = \begin{pmatrix} 1 & 4 \\ 2 & 5 \\ 3 & 6 \end{pmatrix}.$$

In some contexts,  $A'$  is also used to denote the transpose.

# Matrix Representation of the Model

Consider again the linear model

$$y_i = \beta_0 + \sum_{k=1}^K \beta_k x_{i,k} + u_i.$$

Let

$$x_i = \begin{pmatrix} x_{i,1} \\ x_{i,2} \\ \vdots \\ x_{i,K} \end{pmatrix} \in \mathbb{R}^K, \quad \beta = \begin{pmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_K \end{pmatrix} \in \mathbb{R}^K.$$

Then the model can be written as

$$y_i = \beta_0 + x_i^\top \beta + u_i,$$

where  $x_i^\top \beta = \sum_{k=1}^K \beta_k x_{i,k}$ .

[Introduction](#)[Dimension](#)[Various Matrices](#)[Matrix Addition  
and Subtraction](#)[Matrix  
Multiplication](#)[Scalar Multiplication](#)[Matrix Multiplication](#)[Transpose of a  
Matrix](#)[Inverse Matrix](#)[Determinant of a Matrix](#)[Inverse Matrix](#)[Matrix Types](#)

# Properties of the Transpose

For compatible matrices  $A, B$ , scalar  $\alpha$ , and vector  $x$ :

$$\textcircled{1} (A^\top)^\top = A$$

$$\textcircled{2} (\alpha A)^\top = \alpha A^\top$$

$$\textcircled{3} (A + B)^\top = A^\top + B^\top$$

$$\textcircled{4} (AB)^\top = B^\top A^\top$$

$$\textcircled{5} x^\top x = \sum_{i=1}^n x_i^2$$

# A Useful Example

If

$$A = \begin{pmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{pmatrix},$$

where each  $a_i$  is a  $1 \times k$  row vector, then

$$A^T = (a_1^T, a_2^T, \dots, a_n^T).$$

So the rows of  $A$  become the columns of  $A^T$ .

# Why is $X^T X$ Symmetric?

Let  $X$  be an  $n \times k$  matrix. Then  $X^T$  is a  $k \times n$  matrix.

We want to show that  $X^T X$  is symmetric:

$$(X^T X)^T = X^T X.$$

Using  $(AB)^T = B^T A^T$ ,

$$(X^T X)^T = X^T (X^T)^T = X^T X.$$

Therefore,  $X^T X$  is symmetric.

# Determinant of a Matrix

The determinant is a scalar value computed from a square matrix.

- For

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad \det(A) = ad - bc.$$

- For

$$A = \begin{pmatrix} a & b & c \\ d & e & f \\ g & h & i \end{pmatrix},$$

$$\det(A) = a(ei - fh) - b(di - fg) + c(dh - eg).$$

# Properties of the Determinant

For a square matrix  $A$ :

- 1 If  $\det(A) = 0$ , then  $A$  is singular and does not have an inverse.
- 2 If  $\det(A) \neq 0$ , then  $A$  is non-singular and has an inverse.
- 3  $\det(I) = 1$ .
- 4  $\det(AB) = \det(A) \det(B)$ .

# Inverse Matrix

The inverse of a matrix  $A$ , denoted by  $A^{-1}$ , is the matrix satisfying

$$AA^{-1} = A^{-1}A = I.$$

A square matrix has an inverse if and only if

$$\det(A) \neq 0.$$

# What Does the Existence of $A^{-1}$ Mean?

If  $A^{-1}$  exists, then the linear transformation by  $A$  can be undone:

$$A^{-1}A = AA^{-1} = I.$$

So  $A^{-1}$  is not just “division by a matrix”. It is the matrix that reverses the transformation represented by  $A$ .

If  $A^{-1}$  does not exist, then some information is lost and the original vector cannot always be recovered uniquely.

# Formula for the Inverse

If  $A$  is a square matrix with  $\det(A) \neq 0$ , then

$$A^{-1} = \frac{1}{\det(A)} \operatorname{adj}(A),$$

where  $\operatorname{adj}(A)$  is the adjugate matrix.

For a  $2 \times 2$  matrix

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix},$$

we have

$$A^{-1} = \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}, \quad \text{if } ad - bc \neq 0.$$

[Introduction](#)[Dimension](#)[Various Matrices](#)[Matrix Addition  
and Subtraction](#)[Matrix  
Multiplication](#)[Scalar Multiplication](#)[Matrix Multiplication](#)[Transpose of a  
Matrix](#)[Inverse Matrix](#)[Determinant of a Matrix](#)[Inverse Matrix](#)[Matrix Types](#)

# Example of an Inverse

Let

$$A = \begin{pmatrix} 2 & 1 \\ 3 & 4 \end{pmatrix}.$$

Then

$$\det(A) = 2 \cdot 4 - 1 \cdot 3 = 5.$$

Hence,

$$A^{-1} = \frac{1}{5} \begin{pmatrix} 4 & -1 \\ -3 & 2 \end{pmatrix}.$$

# Matrix Types: Definite and Semi-Definite

For a symmetric matrix  $A \in \mathbb{R}^{n \times n}$ , the sign of the quadratic form

$$x^{\top}Ax$$

is important.

- **Positive definite:**

$$x^{\top}Ax > 0 \quad \text{for all } x \neq 0$$

- **Positive semidefinite:**

$$x^{\top}Ax \geq 0 \quad \text{for all } x$$

- **Negative definite:**

$$x^{\top}Ax < 0 \quad \text{for all } x \neq 0$$

- **Negative semidefinite:**

$$x^{\top}Ax \leq 0 \quad \text{for all } x$$

- **Indefinite:**  $x^{\top}Ax$  can take both positive and negative values.

# Positive Definite Matrix

A symmetric matrix  $A \in \mathbb{R}^{n \times n}$  is called **positive definite** if

$$x^{\top}Ax > 0 \quad \text{for all } x \neq 0.$$

If

$$x^{\top}Ax \geq 0 \quad \text{for all } x,$$

then  $A$  is called **positive semidefinite**.

# How Can We Check It?

There are several ways to check whether a symmetric matrix is positive definite.

- **Directly from the quadratic form:** compute  $x^T Ax$  and check whether it is always positive for  $x \neq 0$ .
- **Eigenvalues:**  $A$  is positive definite if and only if all eigenvalues of  $A$  are positive.
- **Leading principal minors:** for a symmetric matrix,  $A$  is positive definite if all leading principal minors are positive.

For  $2 \times 2$  matrices, these checks are often simple.

## Example: A $2 \times 2$ Matrix

Consider

$$A = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}.$$

For  $x = (x_1, x_2)^\top$ ,

$$x^\top Ax = (x_1 \quad x_2) \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = 2x_1^2 + 2x_1x_2 + 2x_2^2.$$

We can rewrite this as

$$x_1^2 + (x_1 + x_2)^2 + x_2^2 > 0 \quad \text{for all } x \neq 0.$$

Therefore,  $A$  is positive definite.

# A Useful Criterion for $2 \times 2$ Matrices

For a symmetric matrix

$$A = \begin{pmatrix} a & b \\ b & c \end{pmatrix},$$

$A$  is positive definite if

$$a > 0 \quad \text{and} \quad \det(A) = ac - b^2 > 0.$$

This is a special case of the leading principal minor condition.

# Why is a Positive Definite Matrix Important?

- A positive definite matrix is always **invertible**.
- Since  $x^T Ax > 0$  for all  $x \neq 0$ , it plays an important role in **quadratic optimisation**.
- In econometrics,

$$\hat{\beta} = (X^T X)^{-1} X^T y$$

requires  $X^T X$  to be invertible.

- In statistics, covariance matrices satisfy

$$a^T \Sigma a = \text{Var}(a^T X) \geq 0.$$

Therefore, positive definite and positive semidefinite matrices play an important role in linear algebra, statistics, and econometrics.
